Abstract

Burnout has emerged as a global health concern, with its prevalence notably increasing during the COVID-19 pandemic. This especially occurs among individuals working within the field of healthcare. In order to contribute to the improvement of working conditions and mental health, this study replicates a mediation model previously tested by Grass et al. (2018) among teaching students and by Zerna et al. (2022) among teachers. For this purpose, multiple mediation models, using a sample of N = 642 healthcare workers were examined. The incorporated predictor was Need for Cognition (an intrinsic motivation to engage with cognitively demanding thoughts). Mediators were self-control, the emotion regulation strategies reappraisal and suppression, as well as adaptive and maladaptive coping strategies. The burnout subdimensions reduced personal efficiency, emotional exhaustion, and depersonalization each functioned individually as outcome variables. In addition to the mediation analyses, correlation analyses of these variables were also calculated. The results confirmed that adaptive coping strategies functioned preventively across all burnout dimensions. Furthermore, reappraisal and maladaptive coping mediated the relationship between NFC and some subdimensions of burnout. Healthcare workers who tended towards higher NFC appeared to be protected from burnout development due to various tested mediators. Regarding the daily work environment, initial evidence suggests that efforts should be made to particularly promote adaptive coping strategies. Future studies should further examine the link between NFC and burnout among healthcare professionals.

Keywords: Need for Cognition, burnout, self-control, emotion regulation, coping

Word count: X

Need for Cognition and Burnout in healthcare: The mediating role of self-control, emotion regulation, and coping strategies

Burnout is a psychological, work-related stress syndrome and a global health concern (Maslach, 2003; Parandeh et al., 2022). It correlates with depression (Bianchi et al., 2015), increased alcohol abuse (Oreskovich et al., 2012), and a heightened risk of suicidal thoughts (Shanafelt et al., 2011). As a response to excessive work stress (Maslach, 1998), burnout affects not only individuals but also their workplace (West et al., 2018), leading to decreased productivity (Dewa et al., 2017), reduced job satisfaction, and intentions to leave the profession (Shanafelt et al., 2009).

Occupational stress is a growing problem, especially among healthcare workers (Rink et al., 2023). Challenges like time constraints, lack of control, and competing demands are significant job strains (Lyndon, 2015). The COVID-19 pandemic further exacerbated burnout rates (Galanis et al., 2021; Prasad et al., 2021), as healthcare workers faced higher health risks, increased workloads, inadequate equipment, and limited resources. These strains impacted not only the workers but also the quality of patient care, leading to lower patient satisfaction and increased medical errors (West et al., 2018).

The rising number of burnout cases underscores its significance in today's society. Despite extensive research, the exact causes and antecedents of burnout are not fully understood. This study investigates the relationship between burnout, its underlying mechanisms, and protective factors, extending previous research on factors mediating the role of cognitive motivation in burnout (Grass et al., 2018; Zerna et al., 2022) from aspiring and experienced teachers to healthcare professionals. The following section explains the mediation model and its variables.

Theoretical Framework

. . .

The present study

⁶⁶ . . .

Correlational Research Questions and Hypotheses. RQ1: Is there a relationship between Need for Cognition (NFC), self-control, adaptive and maladaptive coping strategies, the emotion regulation strategies reappraisal and suppression, as well as the burnout dimension reduced personal efficiency (rPE)?

- H1a: There will be a moderate positive relationship between NFC and self-control.

- H1b: There will be a small positive relationship between NFC and reappraisal and no relationship between NFC and suppression.

- H1c: There will be a moderate positive relationship between NFC and adaptive coping and a small negative relationship between NFC and maladaptive coping.

- H1d: There will be a medium negative relationship between NFC and rPE.

- H1e: There will be a large negative relationship between self-control and rPE.

- H1f: There will be a medium negative relationship between reappraisal and rPE and a no relationship between suppression and rPE.

- H1g: There will be a large negative relationship between adaptive coping and rPE and a large positive relationship between maladaptive coping and rPE.

RQ2: Is there a relationship between NFC, self-control, adaptive and maladaptive coping strategies, the emotion regulation strategies reappraisal and suppression, as well as the burnout dimension emotional exhaustion?

RQ3: Is there a relationship between NFC, self-control, adaptive and maladaptive coping strategies, the emotion regulation strategies reappraisal and suppression, as well as the burnout dimension depersonalization?

Mediational Research Questions and Hypotheses. RQ4: To what extent do self-control, adaptive and maladaptive coping strategies, as well as the emotion regulation strategies reappraisal and suppression mediate the relationship between NFC and the burnout dimension rPE?

- H4a: The relationship between NFC and rPE will not be mediated by self-control. However, higher NFC will be associated with more self-control, whereby self-control will not be associated with rPE.

- H4b: The relationship between NFC and rPE will be partly mediated by reappraisal, whereby a higher NFC is associated with higher reappraisal, which, in turn is associated with lower rPE.

- H4c: The relationship between NFC and rPE will not be mediated by suppression.

- H4d: The relationship between NFC and rPE will be partly mediated by adaptive coping, whereby a higher NFC is associated with more adaptive coping, which, in turn is associated with lower rPE.

- H4e: The relationship between NFC and rPE will be partly mediated by maladaptive coping. A higher NFC is associated with less maladaptive coping, and, in turn, less maladaptive coping is associated with lower rPE.

RQ5: To what extent do self-control, adaptive and maladaptive coping strategies, as well as the emotion regulation strategies reappraisal and suppression mediate the relationship between NFC and the burnout dimensions emotional exhaustion?

RQ6: To what extent do self-control, adaptive and maladaptive coping strategies, as well as the emotion regulation strategies reappraisal and suppression mediate the relationship between NFC and the burnout dimensions depersonalization?

¹¹¹ **Methods**

¹¹²   We report how we determined our sample size, all data exclusions, all manipulations,

¹¹³ and all measures in the study (cf. Simmons et al., 2012).

Procedure
¹¹⁴

¹¹⁵   The preregistration of the current study is available at https://osf.io/d6y9k. Data

¹¹⁶ acquisition took place at two separate assessment occasions in the context of academic

¹¹⁷ thesis projects (Kadur, 2018; Ziessler, 2019). For the 2018 investigation (ref.

¹¹⁸ V-259-15-AS-NFC-28032018), the Ethics Committee of Chemnitz University of Technology

¹¹⁹ found no ethical relevance, so no full application was required. For the 2019 study (ref.

¹²⁰ V-336-15-AS-Ressourcen-16052019), a full application was submitted and positively

¹²¹ reviewed, with no ethical concerns raised. To recruit participants, recruitment letters were

¹²² sent to clinics, residential and retirement homes, institutes for higher education, and other

¹²³ health facilities across several German cities in the federal states of Saxony and Hesse.

¹²⁴ Additionally, multiple calls for participants were made on social media platforms, such as

¹²⁵ Facebook and WhatsApp, and recruitment letters were emailed to friends and

¹²⁶ acquaintances working in the field of healthcare. Eligibility requirements for the study

¹²⁷ included a minimum age of 18 years, proficiency in the German language, and current

¹²⁸ employment in a healthcare profession. Data were assessed via anonymous, cross-sectional

¹²⁹ online surveys using the Enterprise Feedback Suite Survey platform (EFS, Questback,

¹³⁰ 2017). Participants were informed about the study's objectives, duration, and data

¹³¹ security. Further, they were given the opportunity to participate in a cash raffle, where €25

¹³² were handed out to two participants for every 100 individuals who took part in the study.

¹³³ As additional reimbursement, participants were offered to receive the study results on

¹³⁴ request as well as information on the personal and work-related risk factors of burnout.

¹³⁵ Before the subjects reported demographic information and completed the questionnaires,

136 participants declared their consent for data security and study participation. At the end of

137 the survey, a control item was included to ensure that participants indicated whether they

138 answered the questions sincerely. Finally, those interested in the raffle could provide their

139 email address which was recorded separately from the scientific data.

140 **Participants**

141   After the exclusion of participants because of incorrect scale labeling, missing consent

142 to be interviewed, double participation, not having answered the questions seriously, not

143 working in a healthcare profession or not being educated to do so, or having taken less

144 than the average time to complete the questionnaires (see pregistration

145 https://osf.io/d6y9k, section Data exclusion for details), the usable subsamples comprised

146 $n_{2018} = 431$, and $n_{2019} = 229$ participants. The resulting total sample therefore consisted of

147 $N = 642$ (547 female, 94 male, 1 diverse; age range 18 to 78 years, $M = 38.3$, $SD = 12.0$

148 years). The majority of participants worked as nurses (46.3%), while 2.8% held

149 management positions in healthcare. Others were employed as social workers (9.8%),

150 psychotherapists (8.4%), and other therapeutic professions such as occupational therapist

151 or healthcare volunteers. Detailed demographic data are provided in Supplementary Table

152 S1. In both studies, the sample sizes were constrained by the number of participants that

153 could be recruited during the limited timeframe of the respective thesis projects. **Post-hoc**

154 **power analysis of achieved power . . .**

155 **Material**

156   All questionnaires used were administered in German language. The reliabilities

157 (MacDonald's ω and Cronbach's α) of the inventories used can be found in Table 1. The

158 burnout dimensions *reduced personal efficiency*, *emotional exhaustion*, and

159 *depersonalization* were assessed using the German version of the 22-item Maslach Burnout

160 Inventory (MBI-D, Büssing & Perrar, 1992). Items such as "I feel burned out by my job."

161 were rated on a scale from 1 (does not occur at all) to 6 (occurs very often/strongly). The

162 internal consistencies of the MBI-D subscales showed good to excellent reliabilities,

163 MacDonald's $\omega \geq = .82$.

164   NFC was assessed with the 16-item short version of the German NFC scale (NCS,

165 Bless et al., 1994) with items like "I like it when my life is full of tricky tasks that I have to

166 solve." These items were rated on a seven-point rating scale ranging from +3 (very

167 accurate) to –3 (completely inaccurate). The scale demonstrated an excellent internal

168 consistency of MacDonald's $\omega = .91$.

169   Self-control was measured by the 13-item short form of the Self-Control Scale

170 (SCS-K-D, Bertrams & Dickhäuser, 2009). Here, a five-point Likert scale from 1

171 (completely inaccurate) to 5 (completely accurate) was used to answer questions like "I am

172 good at resisting temptations." This scale showed an acceptable internal consistency of

173 MacDonald's $\omega = .79$.

174   Further, the Emotion Regulation Questionnaire (ERQ-D, Abler & Kessler, 2009),

175 which included 10 items, was used to assess reappraisal and suppression. Reappraisal was

176 measured by items like "When I get into a stressful situation, I change my thoughts about

177 the situation, so it calms me down." Suppression was determined by items such as "I keep

178 my feelings to myself." Participants responded on a scale ranging from 1 (not true at all) to

179 7 (absolutely true). The six-item reappraisal subscale and the four-item suppression

180 subscale showed good reliability with MacDonald's $\omega \geq .81$.

181   Finally (and differing from the material used by Grass et al. (2018)), the 20-item

182 Stress and Coping Inventory (SCI, Satow, 2012) was used to measure adaptive and

183 maladaptive coping strategies on a scale ranging from 1 (does not apply) to 4 (applies

184 exactly). Adaptive coping was assessed by the subscales "positive thinking", "active stress

185 management", "social support", and "holding on to faith". These subscales, consisting of 16

186 items such as "When stress and pressure arise, I directly address the causes," altogether

demonstrated a good internal consistency, MacDonald's Omega $\omega = .85$. Maladaptive coping was measured with the "increased alcohol and cigarette consumption" subscale, containing four items like "When I am under too much stress, I smoke a cigarette." This subscale had a questionable internal consistency of MacDonald's $\omega = .63$.

Statistical analyses

We used R (Version 4.5.1; R Core Team, 2024) and the R-packages *dplyr* (Version 1.1.4; Wickham et al., 2023), *here* (Version 1.0.1; Müller, 2020), *lavaan* (Version 0.6.19; Rosseel, 2012), *papaja* (Version 0.1.3; Aust & Barth, 2024), *psych* (Version 2.5.3; Revelle, 2024), *RStudio* (Posit Team, 2024), *shape* (Version 1.4.6.1; Soetaert, 2024) and *tinylabels* (Version 0.2.5; Barth, 2025) for all our analyses.

Robust tests were used to account for deviation from univariate and multivariate normality of the study variables, i.e. the MBI subscales, NFC, self-control, emotion regulation strategies, and coping styles; Shapiro-Wilk and Mardia tests, all $p \geq .001$). Spearman correlations were calculated to address the research questions (RQ) regarding bivariate relationships between Need for Cognition (NFC), self-control, adaptive and maladaptive coping strategies, the emotion regulation strategies reappraisal and suppression with the burnout dimensions *reduced personal efficiency* (rPE; RQ1), *emotional exhaustion* (EE; RQ2), and *depersonalization* (DE; RQ3). Statistical significance was evaluated based on the correlations' 95% CI not including zero, which with our sample size was the case for all $|r_s| \geq .077$. Effect size classification followed empirically derived thresholds (Gignac & Szodorai, 2016), i.e., $r_s \geq .10$, .20, and .30 for small, medium, and large correlations. To address the research questions on possible mediation effects, i.e., whether self-control, reappraisal and suppression, and adaptive and maladaptive coping mediate the relationship between NFC and the burnout dimensions rPE (RQ4), EE (RQ5), and DE (RQ6), multiple mediation models were tested using *lavaan* with robust Maximum Likelihood estimation of standard errors.

₂₁₃   **Results**

₂₁₄   Table 1 shows bivariate Spearman correlations between the study variables. Results

₂₁₅ for research questions 1–3 are summarized below.

₂₁₆   **Research Question 1.**   We examined links between Need for Cognition (NFC),

₂₁₇ self-control, the habitual use of the emotion strategies reappraisal and suppression, coping

₂₁₈ strategies, and *reduced personal efficiency.* We observed a large positive correlation

₂₁₉ between NFC and self-control, $r_s = .56$, 95% CI [.51, .61], $p < .001$ (H1a), but no

₂₂₀ correlation with reappraisal, $r_s = .06$, 95% CI [-.02, .14], $p = .128$, or suppression, $r_s =$

₂₂₁ -.01, 95% CI [-.08, .07], $p = .877$ (H1b). NFC showed a small positive correlation with

₂₂₂ adaptive coping, $r_s = .15$, 95% CI [.07, .22], $p < .001$, and a large negative correlation with

₂₂₃ maladaptive coping, $r_s = -.30$, 95% CI [-.37, -.23], $p < .001$ (H1c). *Reduced personal*

₂₂₄ *efficiency* correlated with NFC, $r_s = -.19$, 95% CI [-.26, -.11], $p < .001$, i.e. a small negative

₂₂₅ effect (H1d), self-control, $r_s = -.18$, 95% CI [-.25, -.10], $p < .001$, i.e. a small negative effect

₂₂₆ (H1e), reappraisal and suppression, $r_s = -.29$, 95% CI [-.36, -.21], $p < .001$, i.e. a medium

₂₂₇ negative effect, and $r_s = .12$, 95% CI [.05, .20], $p = .002$, i.e. a small positive effect (H1f), as

₂₂₈ well as adaptive and maladaptive coping, $r_s = -.42$, 95% CI [-.48, -.35], $p < .001$, i.e. a large

₂₂₉ negative effect, and $r_s = .11$, 95% CI [.03, .18], $p = .007$, i.e. a small positive effect (H1g).

₂₃₀   **Research Question 2.**   *Emotional exhaustion* correlated with all variables: NFC,

₂₃₁ $r_s = -.18$, 95% CI [-.26, -.11], $p < .001$, self-control, $r_s = -.14$, 95% CI [-.21, -.06], $p < .001$,

₂₃₂ reappraisal, $r_s = -.15$, 95% CI [-.22, -.07], $p < .001$, and suppression, $r_s = .13$, 95% CI [.06,

₂₃₃ .21], $p < .001$, and both coping strategies, $r_s = -.37$, 95% CI [-.43, -.30], $p < .001$, and $r_s =$

₂₃₄ .22, 95% CI [.14, .29], $p < .001$.

₂₃₅   **Research Question 3.**   For *depersonalization,* no correlations emerged for NFC,

₂₃₆ $r_s = -.07$, 95% CI [-.15, .00], $p = .064$, or self-control, $r_s = -.08$, 95% CI [-.15, .00], $p =$

₂₃₇ .050, but significant ones appeared for reappraisal, $r_s = -.18$, 95% CI [-.25, -.10], $p < .001$,

₂₃₈ suppression, $r_s = .26$, 95% CI [.18, .33], $p < .001$, as well as for both coping strategies, $r_s =$

239 -.28, 95% CI [-.35, -.21], $p < .001$, and $r_s = .15$, 95% CI [.07, .22], $p < .001$.

240   Figures 1–3 summarize the mediation analyses (research questions 4–6). Only

241 standardized coefficients and p-values are reported for ease of reading; full statistics appear

242 in Tables 2–4.

243   **Research Question 4.**   Figure 1 and Table 2 present the results of the multiple

244 mediation analysis for *reduced personal efficiency.* Roughly half of the total effect, $\beta =$

245 $-.22$, $p < .001$, stemmed from the direct path of NFC on reduced personal efficiency, $\beta =$

246 $-.11$, $p = .017$. While NFC predicted self-control, $\beta = .60$, $p < .001$, self-control did not

247 predict reduced personal efficiency, $\beta = -.04$, $p = .371$, hence, no mediation occured, $\beta =$

248 $-.03$, $p = .370$ (H4a). Reappraisal partly mediated the NFC–efficiency link, $\beta = -.01$, $p =$

249 $.049$ (H4b), while suppression did not, $\beta = .00$, $p = .464$ (H4c). Adaptive coping mediated

250 the effect of NFC on reduced personal efficiency, , $\beta = -.07$, $p < .001$ (H4d). Although NFC

251 predicted maladaptive coping, $\beta = -.33$, $p < .001$, a mediation effect of maladaptive coping

252 was not supported, , $\beta = .00$, $p = .921$ (H4e).

253   **Research Question 5.**   Figure 2 and Table 3 show the model for *emotional*

254 *exhaustion.* Less than half of the total effect, $\beta = -.22$, $p < .001$, was due to the direct

255 path, $\beta = -.09$, $p = .078$. Mediation occurred for adaptive coping, $\beta = -.06$, $p < .001$, and

256 maladaptive coping, $\beta = -.05$, $p = .001$, but not for self-control, $\beta = -.02$, $p = .477$,

257 reappraisal, $\beta = .00$, $p = .872$, or suppression, $\beta = .00$, $p = .452$.

258   **Research Question 6.**   Figure 3 and Table 4 show the model for *depersonalization.*

259 About one third of the total effect, $\beta = -.12$, $p < .001$, reflected the direct path, $\beta = -.03$, p

260 $= .493$. Again, mediation was found for adaptive and maladaptive coping, $\beta = -.04$, $p <$

261 $.001$, and $\beta = -.03$, $p = .010$, but not for self-control, $\beta = .00$, $p = .964$, reappraisal, $\beta =$

262 $-.01$, $p = .065$, or suppression, $\beta = -.01$, $p = .420$.
